

Named for the regular \_\_\_\_\_ at which properties \_\_\_\_\_, a result of \_\_\_\_\_ arrangement.

Elements are arranged in order of increasing \_\_\_\_\_ number

**Periods**

**Horizontal** \_\_\_\_\_

Row 1  
Row 2  
Row 3  
Row 4

Sodium is in Period 3 (1 electron in the outer shell)

**Periods**

B	C	N	O	F	Ne
Al	Si	P	S	Cl	Ar
K	Ca	Sc	Ti	V	Cr

Show the number of electron \_\_\_\_\_ an atom has  
Numbered 1 – 7 (e.g., **elements in Period 3 have three shells**)

**The Structure of the Periodic Table**

**Groups**

Numbered 1–7 & 0 (0 instead of Group 8)

Show the number of \_\_\_\_\_ electrons

Sodium is in Group 1 (1 electron in the outer shell)

1	2		3	5	6	0
H	He		B	C	N	O
Li	Be		Al	Si	P	S
Na	Mg		K	Ca	Sc	Ti
K	Ca	Sc	Ti	V	Cr	Mn
Rb	Sr	Y	Zr	Nb	Mo	Tc
Cs	Ba	La	Hf	Ta	W	Re
Fr	Ra	Ac	Rf	Db	Sg	Bh
Ce	Pr	Nd	Pm	Sm	Eu	Gd
Th	Pa	U	Np	Pu	Am	Cm

## How Electronic Structure Relates to the Periodic Table

Feature	Periodic Table Connection	Example: Chlorine (2, 8, 7)
Number of shells	Period	3 - Period 3
Number of electrons in outer shell	_____	7 outer electrons - Group 7
Total number of electrons	_____ number	_____

Elements in the same group have similar \_\_\_\_\_ properties because they have the same number of valence (outer shell) electrons.

### Metals vs. Non-Metals

**Metals:** \_\_\_\_\_ and \_\_\_\_\_ of the table.  
**Non-Metals:** \_\_\_\_\_-hand side.  
**Metalloids:** Border between metals and non-metals.

## Development of the Periodic Table

## C1.2 The Periodic Table

### Early Attempts

Scientists originally arranged elements by atomic \_\_\_\_\_.

- This method led to errors because \_\_\_\_\_ were not known.
- Some elements ended up in the wrong \_\_\_\_\_.

Property	Metals	Non-Metals
Electrical Conductivity	_____	Poor conductor
Heat Conductivity	Good conductor	_____
Appearance	Shiny	_____
Density	High	Low
Malleability	_____	Brittle
Bonding	_____ electrons (form positive ions)	_____/share electrons (form negative ions)

### Dmitri Mendeleev

#### Contribution

- Arranged elements by atomic weight while maintaining group properties.
- Left \_\_\_\_\_ for \_\_\_\_\_ elements, predicting their properties.
- Grouped elements with similar \_\_\_\_\_ properties for better classification.
- Recognised periodic \_\_\_\_\_, forming the basis for the modern periodic table.

#### Limitations

- Ordered by atomic weight instead of atomic number, causing some misplacements.
- Lacked knowledge of \_\_\_\_\_, affecting atomic weight ordering accuracy.
- Couldn't fully explain periodic trends due to limited understanding of \_\_\_\_\_ particles.

### The Modern Periodic Table

The discovery of protons, neutrons, and electrons led to:

- Ordering elements by atomic \_\_\_\_\_ (not weight).
- Explanation of "pair \_\_\_\_\_" due to isotopes.
- Fixing incorrect placements (e.g., Tellurium & Iodine).

In Mendeleev's Periodic Table, Iodine (I) was ordered before Tellurium (Te). The modern table orders them by atomic number, placing Iodine (\_\_\_\_ protons) after Tellurium (\_\_\_\_ protons).

52 <b>Te</b> Tellurium 127.6	53 <b>I</b> Iodine 126.90447
---------------------------------------	---------------------------------------

# Group 0: Noble Gases

Non-\_\_\_\_\_ and do not easily form \_\_\_\_\_.

\_\_\_\_\_ outer shell of electrons → Very \_\_\_\_\_ and unreactive (\_\_\_\_\_)

## Properties

Exist as monatomic gases (\_\_\_\_\_ atoms).

## Trends in Physical Properties

Boiling points \_\_\_\_\_ down the group due to larger atom size and mass, resulting in \_\_\_\_\_ forces that require more \_\_\_\_\_ to overcome.

Element	Boiling Point (°C)
Helium (He)	-269
Neon (Ne)	-246
Argon (Ar)	-186
Krypton (Kr)	-153
Xenon (Xe)	-108
Radon (Rn)	-61

## Why are Noble Gases Unreactive?

Their outermost shell is full (Helium: 2 electrons, others: 8 electrons).

Since they do not need to \_\_\_\_\_, \_\_\_\_\_, or \_\_\_\_\_ electrons, they do not readily react.

Balloons, cooling superconductors (lighter than air, non-flammable)

Used in welding (inert atmosphere)

## Uses

Lights (glows when electricity passes through)

Flash photography, car headlights

Group	Key Features	Trends in Reactivity
Group 0 (Noble Gases)	Unreactive, full outer shell, low boiling points	No trend (inert gases)
Group 1 (Alkali Metals)	Very reactive, soft, low density, low melting points	Increases down the group
Group 7 (Halogens)	Reactive non-metals, form -1 ions, diatomic	Decreases down the group

# Group 1: Alkali Metals

\_\_\_\_\_ metals that can be cut with a knife \_\_\_\_\_ melting points; \_\_\_\_\_ down the group.

## Properties

Low \_\_\_\_\_ (Lithium, Sodium, and Potassium are less \_\_\_\_\_ than water).

1 electron in outer shell → Very \_\_\_\_\_

## C1.2 Groups in the Periodic Table

### Reactions of Halogens

With Metals → Forms \_\_\_\_\_ metal halides (\_\_\_\_\_).  
Equation: Metal + Halogen → Metal Halide  
Example:  $2\text{Na} + \text{Cl}_2 \rightarrow$  (sodium chloride).

With Hydrogen → Forms hydrogen halides (covalent)  
Equation:  $\text{H}_2 + \text{X}_2 \rightarrow$   
Example:  $\text{H}_2 + \text{Cl}_2 \rightarrow$  (hydrogen chloride)

Displacement Reactions: A more reactive halogen displaces a less reactive halogen from its salt solution  
Reactivity Order:  $\text{Cl}_2 > \text{Br}_2 > \text{I}_2$ .

Examples:  
 $\text{Cl}_2 + 2\text{KBr} \rightarrow$   
• Chlorine displaces bromine  
 $\text{Br}_2 + 2\text{KI} \rightarrow$   
• Bromine displaces iodine

### Reactions of Alkali Metals

With Water → Produces hydrogen gas & a metal hydroxide (alkaline solution).  
Equation:  $2\text{M (s)} + 2\text{H}_2\text{O (l)} \rightarrow$  (aq) + \_\_\_\_\_ (g)

Observations:

- Lithium: Fizzes \_\_\_\_\_, moves slowly.
- Sodium: More \_\_\_\_\_, forms a ball, dissolves \_\_\_\_\_.
- Potassium: \_\_\_\_\_ reaction, lilac flame, may explode

With Oxygen → Forms metal oxides.  
Equation:  $4\text{M (s)} + \text{O}_2 \text{ (g)} \rightarrow$  (s)  
Observation: Forms a dull oxide coating when exposed to \_\_\_\_\_.

With Chlorine → Forms metal chlorides (white solids).  
Equation:  $2\text{M (s)} + \text{Cl}_2 \text{ (g)} \rightarrow$  (s)  
Observation: The reaction becomes more \_\_\_\_\_ down the group.

# Group 7: Halogens

Can be toxic and are highly \_\_\_\_\_ Non-metals with \_\_\_\_\_ electrons in the outer shell.

## Properties

Exist as \_\_\_\_\_ atomic molecules (e.g.,  $\text{Cl}_2$ ,  $\text{Br}_2$ ).

Reactivity \_\_\_\_\_ down the group.

## Trends in Physical Properties

Melting and boiling points \_\_\_\_\_ down the group due to larger atoms leading to \_\_\_\_\_ intermolecular forces, which require \_\_\_\_\_ energy to overcome.

## Trends in Physical Properties

Reactivity increases down a group due to additional electron \_\_\_\_\_, which position outer electrons \_\_\_\_\_ from the \_\_\_\_\_. This distance \_\_\_\_\_ the attraction from the nucleus, making it \_\_\_\_\_ to \_\_\_\_\_ outer electrons and thus increasing reactivity.

Element	Density	Melting Point (°C)	Reactivity
Lithium (Li)	0.53 g/cm <sup>3</sup>	181°C	Least reactive
Sodium (Na)	0.97 g/cm <sup>3</sup>	98°C	More reactive
Potassium (K)	0.86 g/cm <sup>3</sup>	63°C	Even more reactive
Rubidium (Rb)	1.53 g/cm <sup>3</sup>	39°C	Highly reactive
Caesium (Cs)	1.93 g/cm <sup>3</sup>	28°C	Extremely reactive
Francium (Fr)	Unstable	~27°C	Most reactive (rare and radioactive)

Element	State at Room Temperature	Colour	Boiling Point (°C)
Fluorine (F <sub>2</sub> )	Gas	Pale yellow	-188°C
Chlorine (Cl <sub>2</sub> )	Gas	Green	-35°C
Bromine (Br <sub>2</sub> )	Liquid	Red-brown	59°C
Iodine (I <sub>2</sub> )	Solid	Dark grey	184°C
Astatine (At <sub>2</sub> )	Solid	Black	302°C

Reactivity \_\_\_\_\_ down the group due to:  
• More electron \_\_\_\_\_, placing the outer shell further from the \_\_\_\_\_.  
• \_\_\_\_\_ attraction for an extra electron.  
• \_\_\_\_\_ is the most reactive; iodine and astatine are the least reactive.
